

Time Series Analysis in AFNI

Outline: 6+ Hours of Edification

- Philosophy (e.g., theory without equations)
- Sample fMRI data
- Theory underlying fMRI analyses: the **HRF**
- “Simple” or “Fixed Shape” regression analysis
 - ☞ Theory and Hands-on examples
- “Deconvolution” or “Variable Shape” analysis
 - ☞ Theory and Hands-on examples
- Advanced Topics (followed by brain meltdown)

Goals: Conceptual Understanding + Prepare to Try It Yourself

Data Analysis Philosophy

- **Signal** = Measurable response to stimulus
- **Noise** = Components of measurement that interfere with detection of signal
- Statistical detection theory:
 - ☞ **Understand** relationship between stimulus & signal
 - ☞ Characterize noise statistically
 - ☞ Can then devise methods to distinguish noise-only measurements from signal+noise measurements, and assess the methods' reliability
 - ☞ Methods and usefulness depend strongly on the assumptions
 - Some methods are “robust” against erroneous assumptions, and some are not

FMRI Philosophy: Signals and Noise

- FMRI Stimulus→Signal connection and noise statistics are both poorly characterized
- Result: there is no “**best**” way to analyze FMRI time series data: there are only “**reasonable**” analysis methods
- To deal with data, must make some assumptions about the signal and noise
- Assumptions will be wrong, but must do ***something***
- Different kinds of experiments require different kinds of analyses
 - ☞ Since signal models and questions you ask about the signal will vary
 - ☞ It is important to **understand** what is going on, so you can select and evaluate “reasonable” analyses

Meta-method for creating analysis methods

- Write down a mathematical model connecting stimulus (or “activation”) to signal
- Write down a statistical model for the noise
- Combine them to produce an equation for measurements given signal+noise
 - ☞ Equation will have unknown parameters, which are to be estimated from the data
 - ☞ N.B.: signal may have zero strength (no “activation”)
- Use statistical detection theory to produce an algorithm for processing the measurements to assess signal presence and characteristics
 - ☞ e.g., least squares fit of model parameters to data

Time Series Analysis on Voxel Data

- Most common forms of fMRI analysis involve fitting an activation+BOLD model to each voxel's time series *separately* (AKA “univariate” analysis)
 - ✎ Some pre-processing steps may do inter-voxel computations
 - e.g., spatial smoothing to reduce noise
- Result of model fits is a set of parameters at each voxel, estimated from that voxel's data
 - ✎ e.g., activation amplitude, delay, shape
 - ✎ “**SPM**” = statistical parametric map
- Further analysis steps operate on individual SPMs
 - ✎ e.g., combining/contrasting data among subjects

Some Features of fMRI Voxel Time Series

- fMRI only measures changes due to neural “activity”
 - ☞ Baseline level of signal in a voxel means little or nothing about neural activity
 - ☞ Also, baseline level tends to drift around slowly (100 s time scale or so)
- Therefore, an fMRI experiment must have at least 2 different neural conditions (“tasks” and/or “stimuli”)
 - ☞ Then statistically test for differences in the MRI signal level between conditions
 - ☞ Many experiments: one condition is “rest”
- Baseline is modeled separately from activation signals, and baseline model includes “rest” periods

Some Sample fMRI Data Time Series

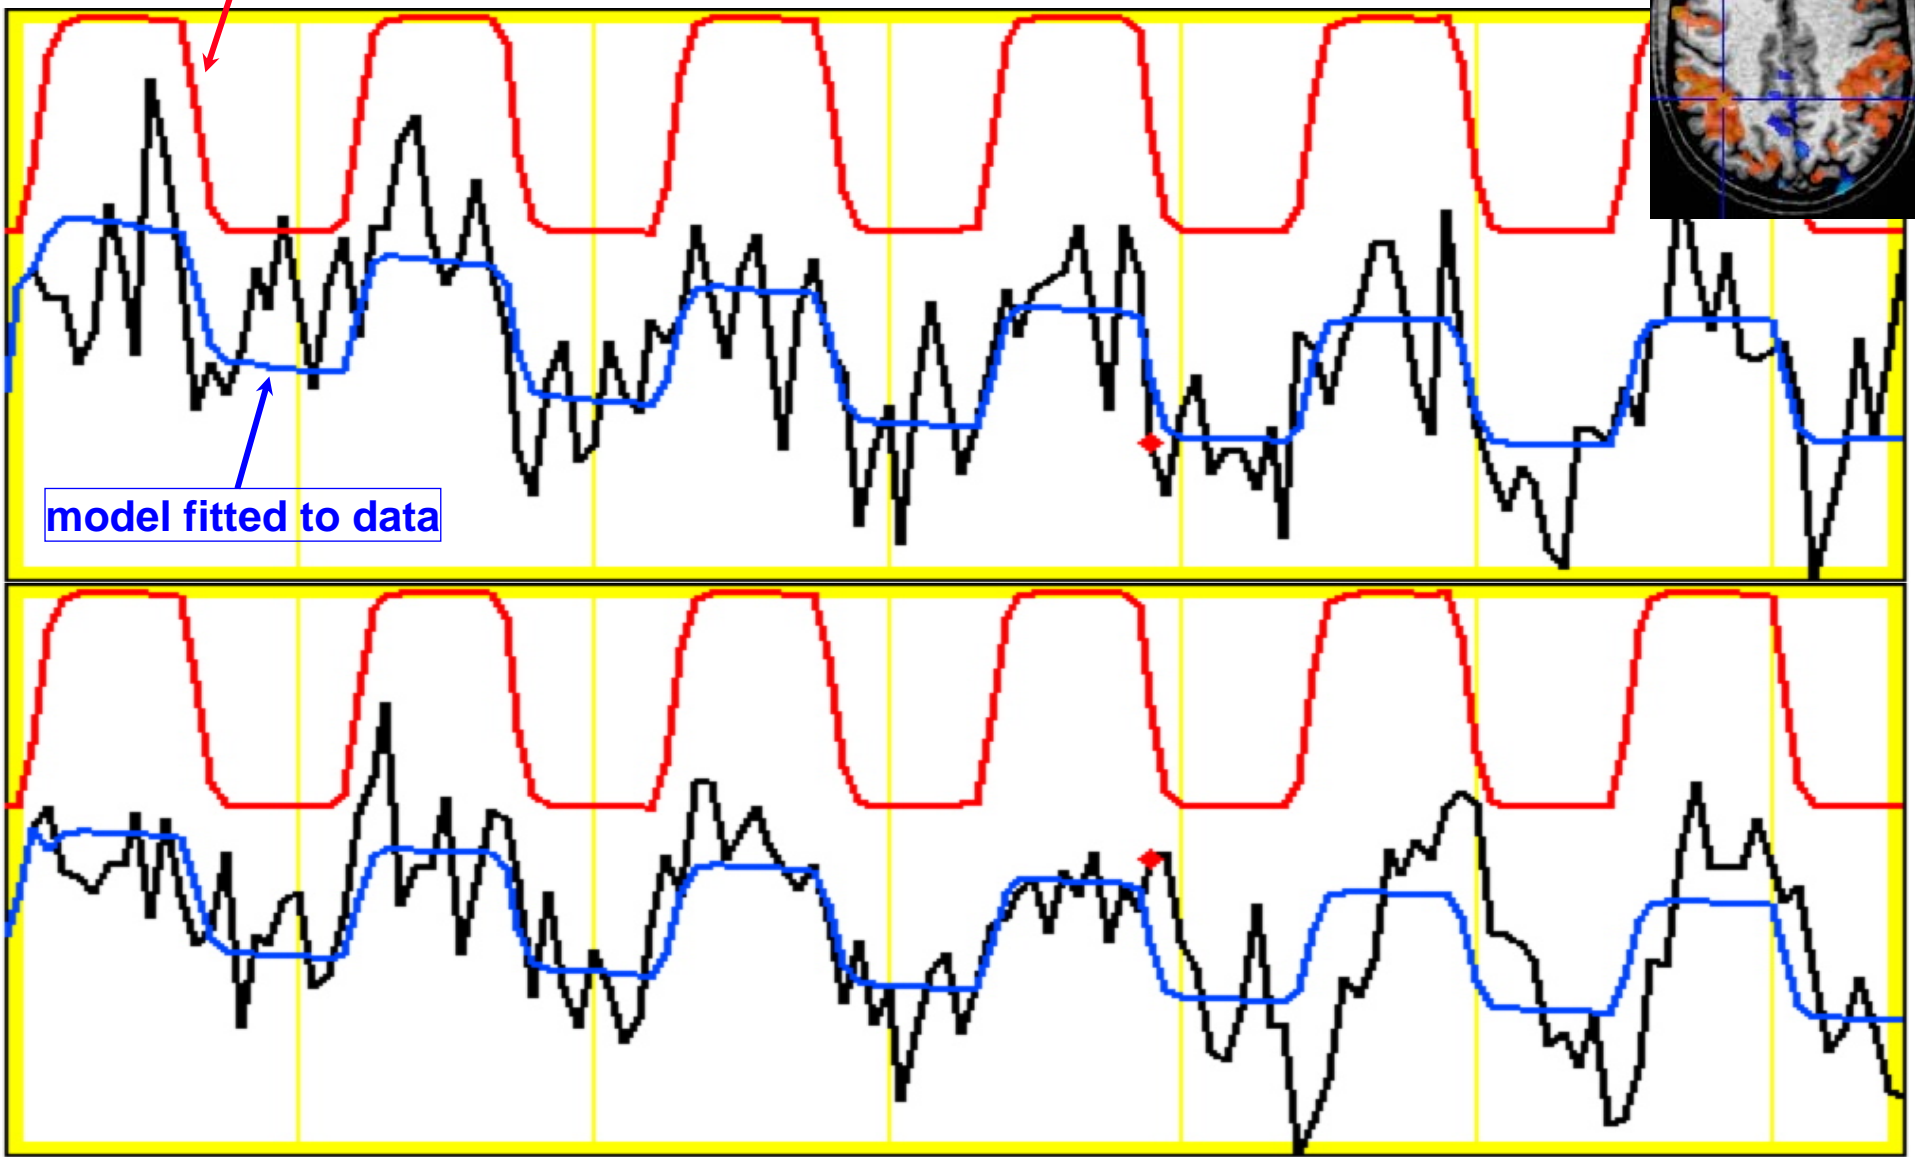

- First: Block-trial fMRI data
 - ✎ “Activation” occurs over a sustained period of time (say, 10 s or longer), usually from more than one stimulation event, in rapid succession
 - ✎ BOLD (hemodynamic) response accumulates from multiple close activations and is large
 - ✎ BOLD response is often visible in time series
- Next 2 slides: same brain voxel in 3 (of 9) EPI runs
 - ✎ **black curve** (noisy) = data
 - ✎ **red curve** (above data) = ideal model response
 - ✎ **blue curve** (within data) = model fitted to data
 - ✎ somatosensory task (finger being rubbed)

Same Voxel: Runs 1 and 2

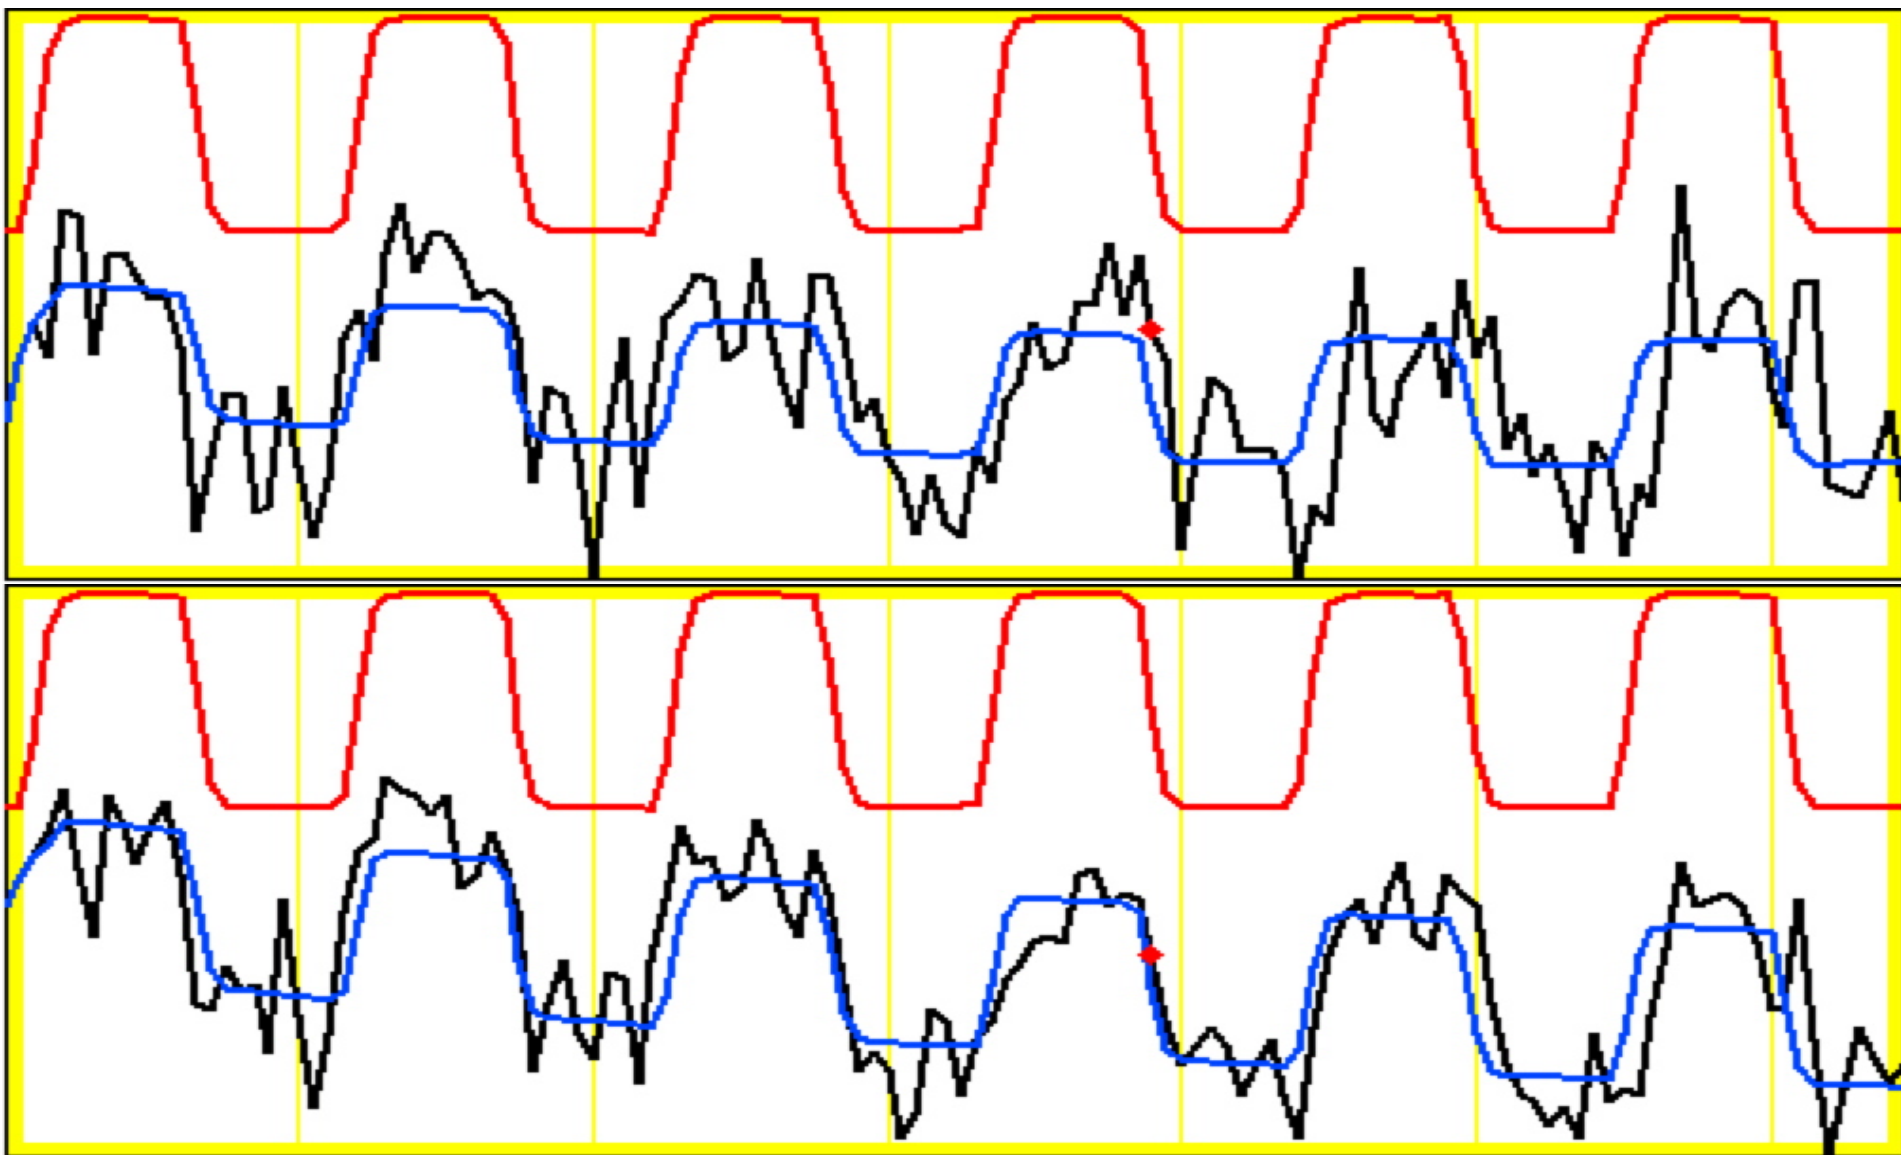

model regressor

model fitted to data

Block-trials: 27 s "on" / 27 s "off"; TR=2.5 s; 130 time points/run

-9- Same Voxel: Run 3 and Average of all 9

⇒ Activation amplitude and shape are variable! Why???

More Sample fMRI Data Time Series

- Second: Event-related fMRI

- ☞ “Activation” occurs in single relatively brief intervals

- ☞ “Events” can be randomly or regularly spaced in time

- If events are randomly spaced in time, signal model itself looks noise-like (to the pitiful human eye)

- ☞ BOLD response to stimulus tends to be weaker, since fewer nearby-in-time “activations” have overlapping hemodynamic responses

- Next slide: Visual stimulation experiment

“Active” voxel shown in next slide

Two Voxel Time Series from Same Run

AXIAL
AFNI!

X: 18	index=112	value=1703	at 224
Y: 31	Grid: 20	Scale: 1.9 pix/datum	Mean: 1689.427
Z: 14	# 0.135	Base: separate	Sigma: 16.33249

Lesson: ER-FMRI activation is not obvious via casual inspection

Hemodynamic Response Function (HRF)

- **HRF** is the idealization of measurable fMRI signal change responding to a single activation cycle (up and down) from a stimulus in a voxel

QuickTime™ and a
GIF decompressor
are needed to see this picture.

Response to brief activation (< 1 s):

- delay of 1-2 s
- rise time of 4-5 s
- fall time of 4-6 s
- model equation:

$$h(t) \propto t^b e^{-t/c}$$

- $h(t)$ is signal change t seconds **after** activation

1 Brief Activation

Linearity of HRF

- Multiple activation cycles in a voxel, closer in time than duration of HRF:

☞ Assume that overlapping responses add

- Linearity is a pretty good assumption
- But not apparently perfect — about 90% correct
- Nevertheless, is widely taken to be true and is the basis for the “general linear model” (GLM) in FMRI analysis

QuickTime™ and a GIF decompressor are needed to see this picture.

Linearity and Extended Activation

- Extended activation, as in a block-trial experiment:
 - ☞ HRF accumulates over its duration (≈ 10 s)

QuickTime™ and a GIF decompressor are needed to see this picture.

- **Black** curve = response to a single brief stimulus
- **Red** curve = activation intervals
- **Green** curve = summed up HRFs from activations
- Block-trials have larger BOLD signal changes than event-related experiments

Convolution Signal Model

- FMRI signal we look for in each voxel is taken to be sum of the individual trial HRFs
 - ☞ Stimulus timing is assumed known (or measured)
 - ☞ Resulting time series (**blue** curves) are called the **convolution** of the HRF with the stimulus timing
- Must also allow for baseline and baseline drifting
 - ☞ Convolution models only the FMRI signal **changes**

• Real data starts at and returns to a nonzero, slowly drifting baseline

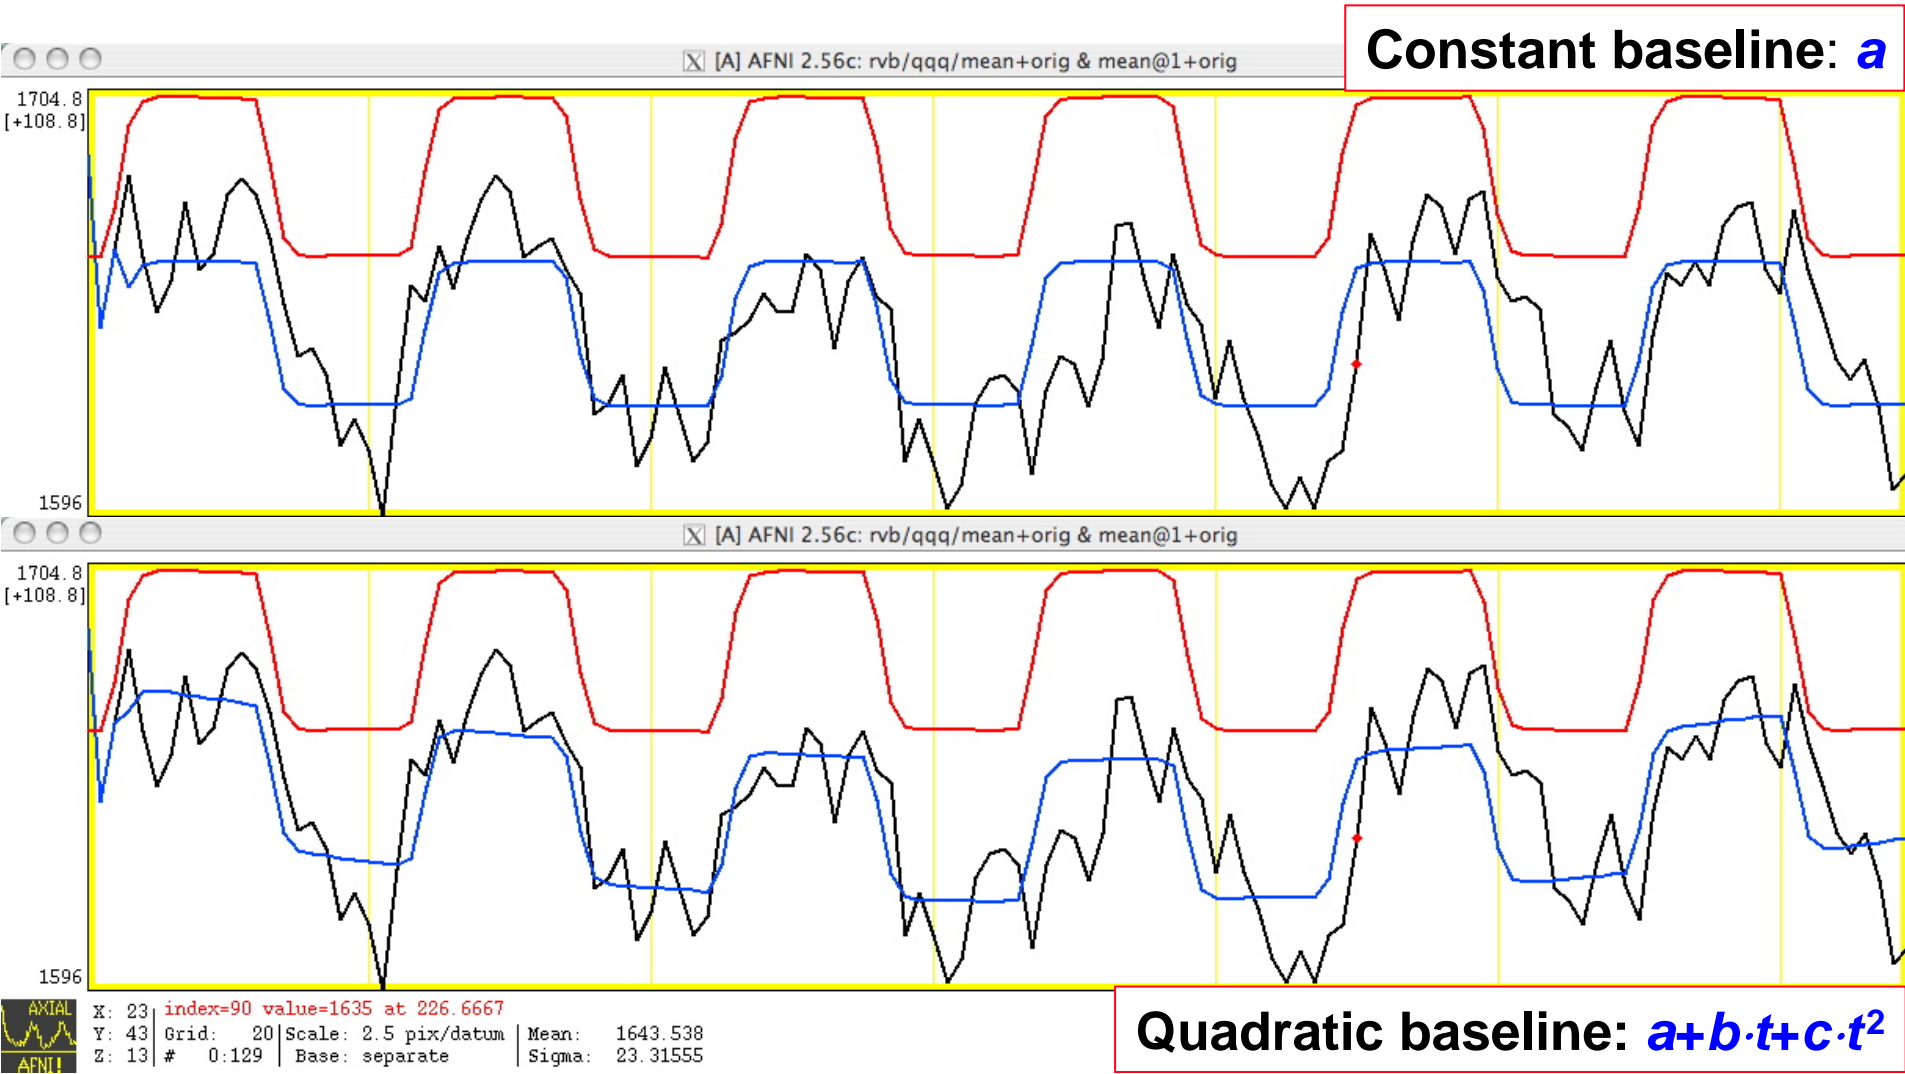

Simple Regression Models

- Assume a fixed shape $h(t)$ for the HRF
 - ✎ e.g., $h(t) = t^{8.6} \exp(-t/0.547)$ [MS Cohen, 1997]
 - ✎ Convolved with stimulus timing (e.g., AFNI program **waver**), get ideal response function $r(t)$
- Assume a form for the baseline
 - ✎ e.g., $a + b \cdot t$ for a constant plus a linear trend
- In each voxel, fit data $Z(t)$ to a curve of the form

$$\underline{Z(t) \approx a + b \cdot t + \beta \cdot r(t)}$$
The signal model!

 - a, b, β are unknown parameters to be calculated in each voxel
 - a, b are “nuisance” parameters
 - β is amplitude of $r(t)$ in data = “how much” BOLD

Simple Regression: Example

Constant baseline: a

Quadratic baseline: $a+b\cdot t+c\cdot t^2$

- Necessary baseline model complexity depends on duration of **continuous** imaging — e.g., 1 parameter per ~150 seconds

Duration of Stimuli - Important Caveats

- Slow baseline drift (time scale 100 s and longer) makes doing fMRI with [long duration](#) stimuli difficult
 - Learning experiment, where the task is done continuously for ~15 minutes and the subject is scanned to find parts of the brain that adapt during this time interval
 - Pharmaceutical challenge, where the subject is given some psychoactive drug whose action plays out over 10+ minutes (e.g., cocaine, ethanol)
- Multiple very [short duration](#) stimuli that are also very close in time to each other are very hard to tell apart, since their HRFs will have 90-95% overlap
 - Binocular rivalry, where percept switches ~ 0.5 s

Is it Baseline Drift? Or Activation?

Sum of HRFs

Is it one extended activation?
Or four overlapping activations?

Individual HRFs

4 stimulus times (**waver** + **1dplot**)

19 s

Multiple Stimuli = Multiple Regressors

- Usually have more than one class of stimulus or activation in an experiment
 - ✦ e.g., want to see size of “**face activation**” vis-à-vis “**house activation**”; or, “**what**” vs. “**where**” activity
- Need to model each separate class of stimulus with a separate response function $r_1(t)$, $r_2(t)$, $r_3(t)$,
 - ✦ Each $r_j(t)$ is based on the stimulus timing for activity in class number j
 - ✦ Calculate a β_j amplitude = amount of $r_j(t)$ in voxel data time series $Z(t)$
 - ✦ Contrast β s to see which voxels have differential activation levels under different stimulus conditions
 - e.g., statistical test on the question $\beta_1 - \beta_2 = 0$?

Multiple Stimuli - Important Caveat

- You do **not** model the baseline condition
 - e.g., “rest”, visual fixation, high-low tone discrimination, or some other simple task
- fMRI can only measure **changes** in MR signal levels between tasks
 - So you need some simple-ish task to serve as a reference point
- The baseline model (e.g., **$a + b \cdot t$**) takes care of the signal level to which the MR signal returns when the “active” tasks are turned off
 - Modeling the reference task explicitly would be redundant (or “collinear”, to anticipate a forthcoming jargon word)

Multiple Regressors: Cartoon

QuickTime™ and a
GIF decompressor
are needed to see this picture.

- Red curve = signal model for class #1
- Green curve = signal model for #2
- Blue curve =
$$\beta_1 \cdot \#1 + \beta_2 \cdot \#2$$
where β_1 and β_2 vary from 0.1 to 1.7 in the animation

- Goal of regression is to find β_1 and β_2 that make the blue curve best fit the data time series
- Gray curve =
$$1.5 \cdot \#1 + 0.6 \cdot \#2 + \text{noise}$$
= simulated data

Multiple Regressors: Collinearity!!

- **Green** curve = signal model for #1
- **Red** curve = signal model for class #2
- **Blue** curve = signal model for #3
- **Purple** curve = **#1 + #2 + #3** which is exactly = 1
- We cannot — *in principle or in practice* — distinguish sum of 3 signal models from constant baseline!!

No analysis can distinguish the cases

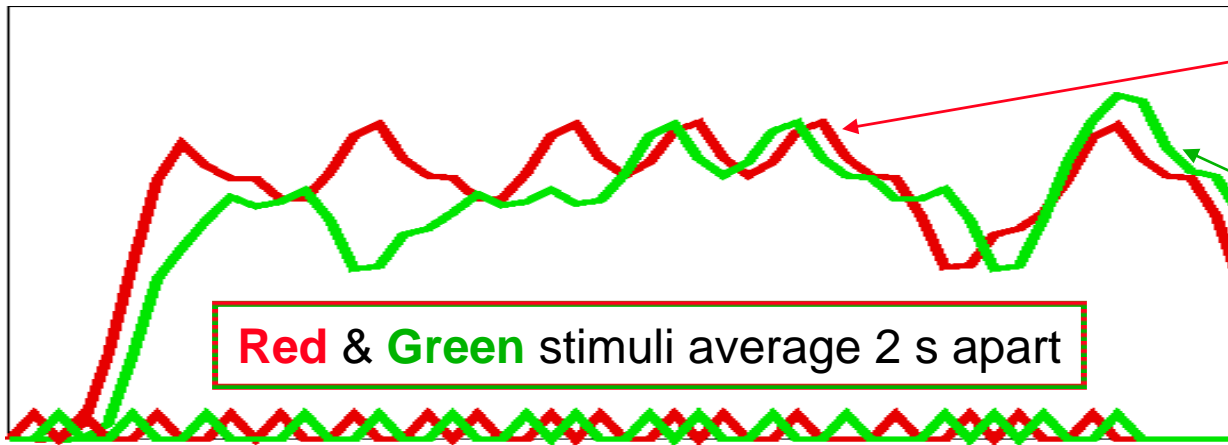

$$Z(t) = 10 + 5 \cdot \#1 \quad \text{and}$$

$$Z(t) = 0 + 15 \cdot \#1 + 10 \cdot \#2 + 10 \cdot \#3$$

and an infinity of other possibilities

Collinear designs are **bad bad bad!**

Multiple Regressors: Near Collinearity

QuickTime™ and a
GIF decompressor
are needed to see this picture.

- **Red** curve = signal model for class #1
- **Green** curve = signal model for #2

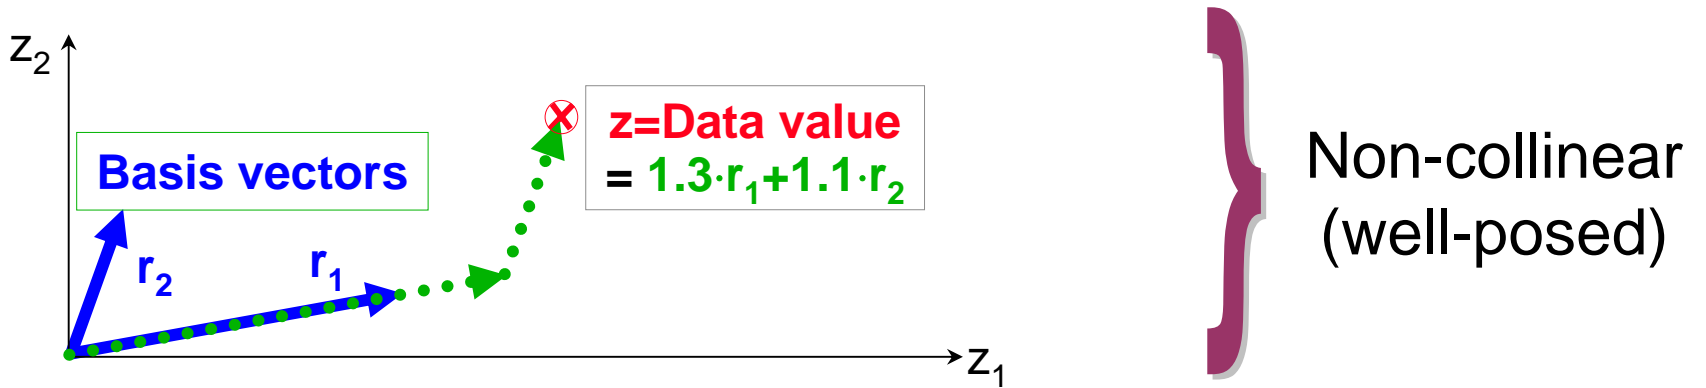

• **Blue** curve =
 $\beta_1 \cdot \#1 + (1 - \beta_1) \cdot \#2$
 where β_1 varies randomly from 0.0 to 1.0 in animation

• **Gray** curve =
 $0.66 \cdot \#1 + 0.33 \cdot \#2$
 = simulated data *with no noise*

- Lots of different combinations of **#1** and **#2** are decent fits to gray curve

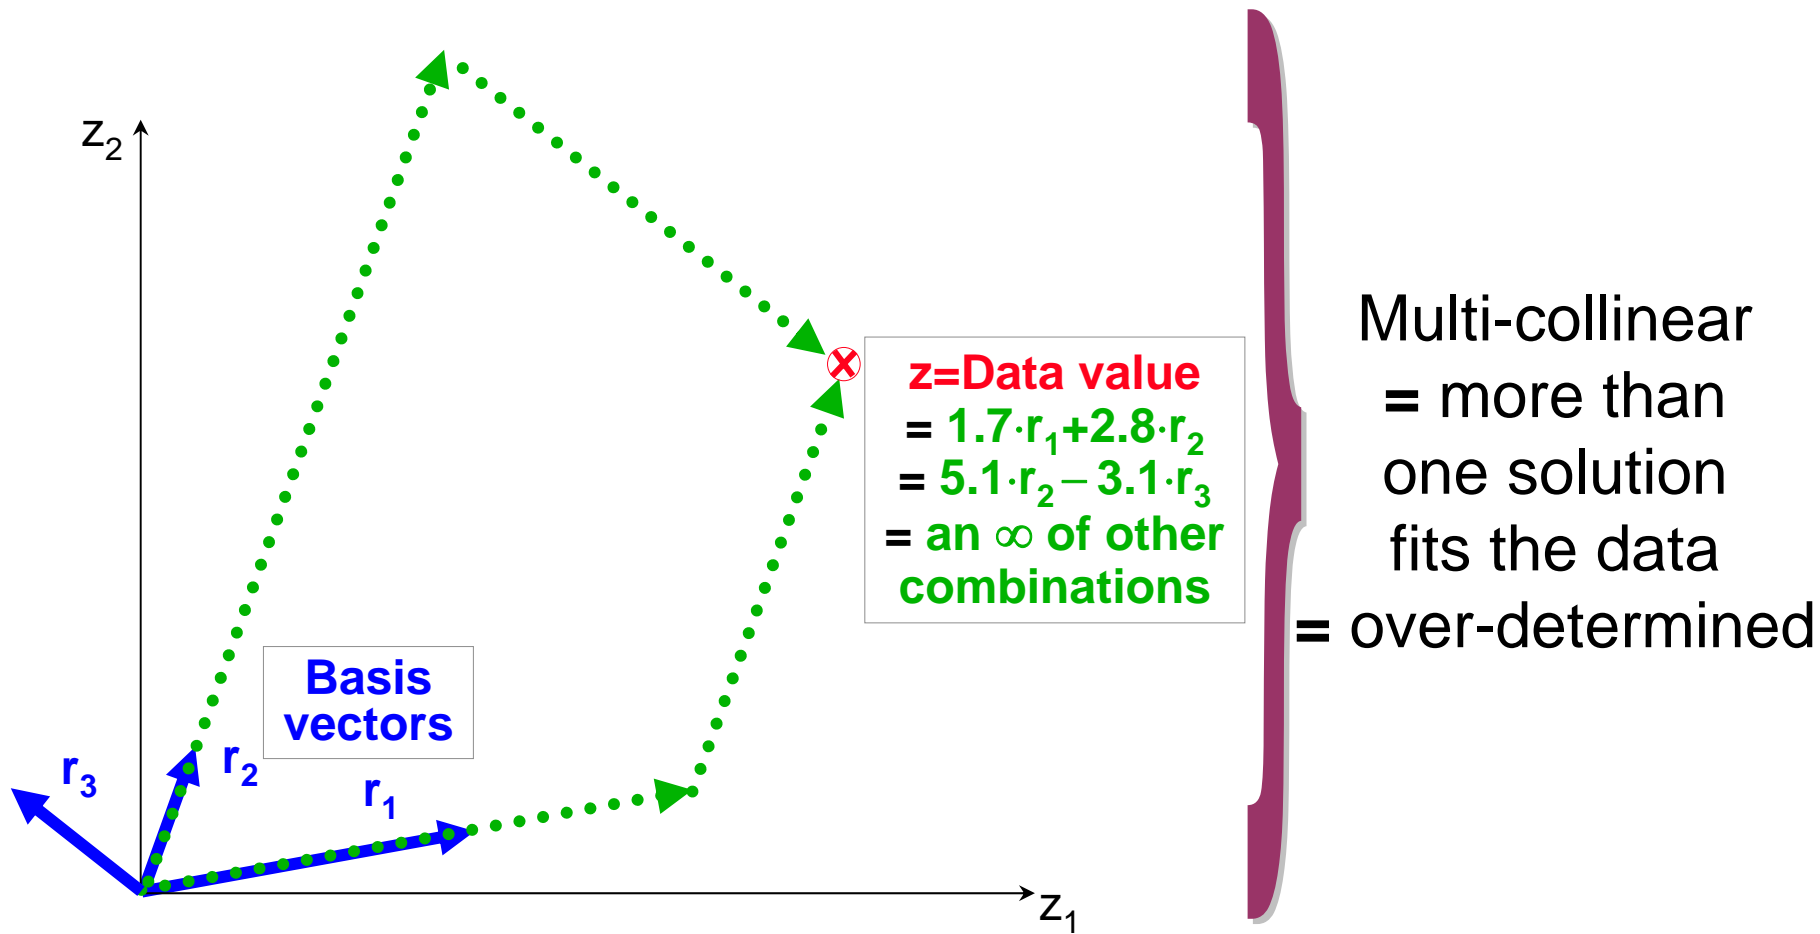

Stimuli are too close in time to distinguish response **#1** from **#2**, considering noise

The Geometry of Collinearity - 1

- Trying to fit data as a sum of basis vectors that are nearly parallel doesn't work well: solutions can be huge
- Exactly parallel basis vectors would be impossible:
 - Determinant of matrix to invert would be zero

The Geometry of Collinearity - 2

- Trying to fit data with too many regressors (basis vectors) doesn't work: no unique solution

Equations: Notation

- Will generally follow notation of Doug Ward's manual for the AFNI program **3dDeconvolve**
- Time: continuous in reality, but in steps in the data
 - ☞ Functions of continuous time are written like $f(t)$
 - ☞ Functions of discrete time expressed like $f(n \cdot TR)$ where $n=0,1,2,\dots$ and TR =time step $=t_n$
 - ☞ Usually use subscript notion f_n as shorthand
 - ☞ Collection of numbers assembled in a column is a

vector and is printed in boldface:

$$\left\{ \begin{array}{l} \text{vector of} \\ \text{length } N \end{array} \right\} = \begin{bmatrix} f_0 \\ f_1 \\ f_2 \\ \bullet \\ f_{N-1} \end{bmatrix} = \mathbf{f}$$

$$\begin{bmatrix} A_{00} & A_{01} & \text{☹} & A_{0,N-1} \\ A_{10} & A_{11} & \text{☹} & A_{1,N-1} \\ \bullet & \bullet & \text{☞} & \bullet \\ A_{M-1,0} & A_{M-1,1} & \text{☹} & A_{M-1,N-1} \end{bmatrix} = \mathbf{A} = \{M \times N \text{ matrix}\}$$

Equations: Single Response Function

- In each voxel, fit data Z_n to a curve of the form

$$Z_n \approx a + b \cdot t_n + \beta \cdot r_n \quad \text{for } n=0, 1, \dots, N-1 \quad (N=\# \text{ time pts})$$
- a , b , β are unknown parameters to be calculated in each voxel
- a, b are “nuisance” baseline parameters
- β is amplitude of $r(t)$ in data = “how much” BOLD
- Baseline model might be more complicated for long (> 150 s) continuous imaging runs:
 - $150 < T < 300$ s: $a + b \cdot t + c \cdot t^2$
 - Longer: $a + b \cdot t + c \cdot t^2 + \lceil T/150 \rceil$ low frequency components
 - Might also include as extra baseline components the estimated subject head movement time series, in order to remove residual contamination from such artifacts

≈ 1 param per 150 s

Equations: Multiple Response Functions

- In each voxel, fit data Z_n to a curve of the form

$$Z_n \approx [\text{baseline}]_n + \beta_1 \cdot r_n^{(1)} + \beta_2 \cdot r_n^{(2)} + \beta_3 \cdot r_n^{(3)} + \text{☹}$$

- β_j is amplitude in data of $r_n^{(j)} = r_j(t_n)$; i.e., “how much” of j^{th} response function in in the data time series

- In simple regression, each $r_j(t)$ is derived directly from stimulus timing **and** user-chosen HRF model

- In terms of stimulus times: $r_n^{(j)} = \sum_{k=1}^{K_j} h(t_n - \tau_k^{(j)})$

- If stimulus occurs on the imaging TR time-grid, stimulus can be represented as a 0-1 time series:

$[s_0^{(j)} \quad s_1^{(j)} \quad s_2^{(j)} \quad s_3^{(j)} \quad \text{☹}]$ where $s_k^{(j)} = 1$ if stimulus # j is on at time $t = k \cdot \text{TR}$, and $s_k^{(j)} = 0$ if # j is off at that time:

$$r_n^{(j)} = h_0 s_n^{(j)} + h_1 s_{n-1}^{(j)} + h_2 s_{n-2}^{(j)} + h_3 s_{n-3}^{(j)} + \text{☹} = \sum_{q=0}^p h_q s_{n-q}^{(j)}$$

Equations: Matrix-Vector Form

- Express **known** data vector as a sum of **known** columns with **unknown** coefficients:

$$\begin{bmatrix} z_0 \\ z_1 \\ z_2 \\ \vdots \\ z_{N-1} \end{bmatrix} \approx \begin{bmatrix} 1 \\ 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix} \cdot a + \begin{bmatrix} 0 \\ 1 \\ 2 \\ \vdots \\ N-1 \end{bmatrix} \cdot b + \begin{bmatrix} r_0^{(1)} \\ r_1^{(1)} \\ r_2^{(1)} \\ \vdots \\ r_{N-1}^{(1)} \end{bmatrix} \cdot \beta_1 + \begin{bmatrix} r_0^{(2)} \\ r_1^{(2)} \\ r_2^{(2)} \\ \vdots \\ r_{N-1}^{(2)} \end{bmatrix} \cdot \beta_2 + \dots$$

- Const baseline
- Linear trend

‘ \approx ’ means “least squares”

or

$$\begin{bmatrix} z_0 \\ z_1 \\ z_2 \\ \vdots \\ z_{N-1} \end{bmatrix} \approx \begin{bmatrix} 1 & 0 & r_0^{(1)} & r_0^{(1)} & \text{☹} \\ 1 & 1 & r_1^{(1)} & r_1^{(1)} & \text{☹} \\ 1 & 2 & r_2^{(1)} & r_2^{(1)} & \text{☹} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & N-1 & r_{N-1}^{(1)} & r_{N-1}^{(2)} & \text{☹} \end{bmatrix} \begin{bmatrix} a \\ b \\ \beta_1 \\ \beta_2 \\ \text{☹} \end{bmatrix}$$

or

the “design” matrix

z depends on the voxel; **R** doesn't

Visualizing the **R** Matrix

- Can graph columns, as shown below
 - But might have 20-50 columns
- Can plot columns on a grayscale, as shown at right
 - Easier to show many columns
 - In this plot, darker bars means larger numbers

Solving $\mathbf{z} \approx \mathbf{R}\boldsymbol{\beta}$ for $\boldsymbol{\beta}$

- Number of equations = number of time points
 - ☞ 100s per run, but perhaps 1000s per subject
- Number of unknowns usually in range 5–50
- Least squares solution: $\hat{\boldsymbol{\beta}} = [\mathbf{R}^T \mathbf{R}]^{-1} \mathbf{R}^T \mathbf{z}$
 - ☞ $\hat{\boldsymbol{\beta}}$ denotes an *estimate* of the true (unknown) $\boldsymbol{\beta}$
 - ☞ From $\hat{\boldsymbol{\beta}}$, calculate $\hat{\mathbf{z}} = \mathbf{R}\hat{\boldsymbol{\beta}}$ as the *fitted model*

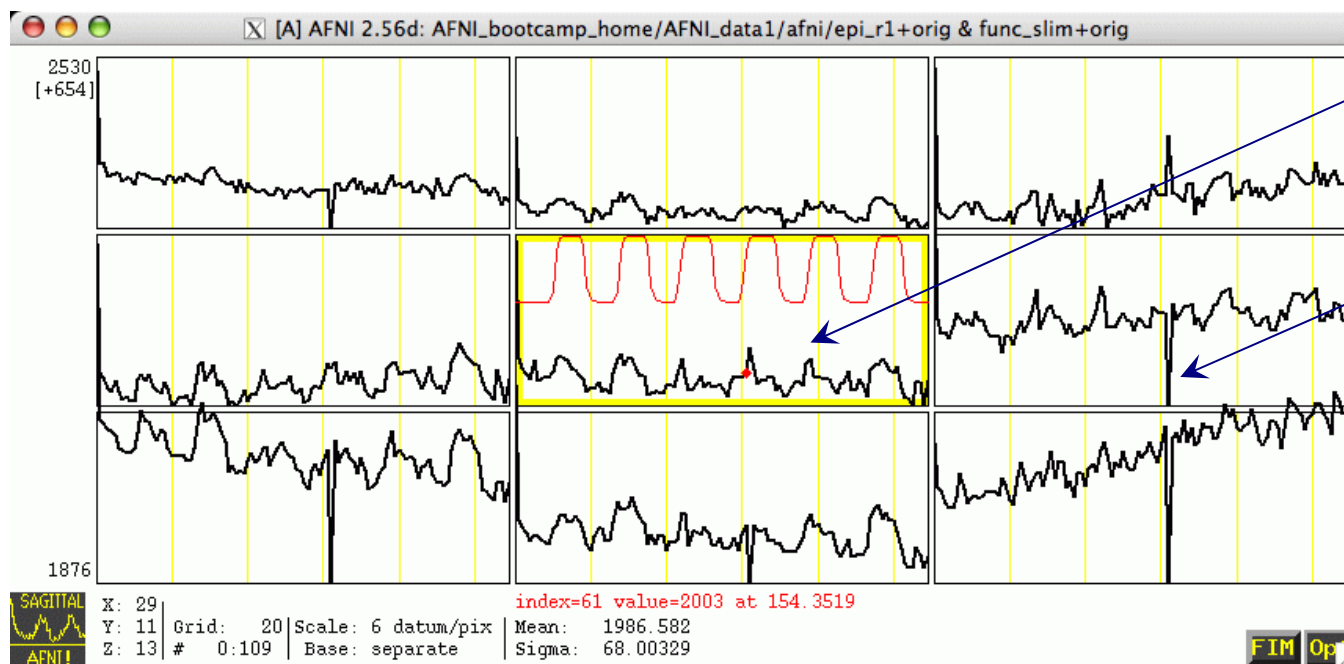

- $\mathbf{z} - \hat{\mathbf{z}}$ is the **residual time series** = noise (we hope)
- Collinearity: when matrix $\mathbf{R}^T \mathbf{R}$ can't be inverted
 - ☞ Near collinearity: when inverse exists but is huge

Simple Regression: Recapitulation

- Choose HRF model $h(t)$ [AKA *fixed-model regression*]
- Build model responses $r_n(t)$ to each stimulus class
 - ↳ Using $h(t)$ and the stimulus timing
- Choose baseline model time series
 - ↳ Constant + linear + quadratic + movement?
- Assemble model and baseline time series into the columns of the \mathbf{R} matrix
- For each voxel time series \mathbf{z} , solve $\mathbf{z} \approx \mathbf{R}\beta$ for $\hat{\beta}$
- **Individual subject maps:** Test the coefficients in $\hat{\beta}$ that you care about for statistical significance
- **Group maps:** Transform the coefficients in $\hat{\beta}$ that you care about to Talairach space, and perform statistics on these $\hat{\beta}$ values

Sample Data Analysis: Simple Regression

- Enough theory (for now: more to come later!)
- To look at the data: type `cd AFNI_data1/afni` ; then `afni`
- **Switch Underlay** to dataset `epi_r1`
 - ☞ Then Sagittal **Image** and **Graph**
 - ☞ **FIM**→**Pick Ideal** ; then click `afni/ideal_r1.1D` ; then **Set**
 - ☞ Right-click in image, **Jump to (ijk)**, then `29 11 13`, then **Set**

- Data clearly has activity in sync with reference
- Data also has a big spike, which is annoying
 - Subject head movement!

Preparing Data for Analysis

- Six preparatory steps are common:
 - ☞ Image registration (realignment): program 3dvolreg
 - ☞ Image smoothing: program 3dmerge
 - ☞ Image masking: program 3dClipLevel or 3dAutomask
 - ☞ Conversion to percentile: programs 3dTstat and 3dcalc
 - ☞ Censoring out time points that are bad: program 3dToutcount or 3dTqual
 - ☞ Catenating multiple imaging runs into 1 big dataset: program 3dTcat
-
- Not all steps are necessary or desirable in any given case
 - In this first example, will only do registration, since the data obviously needs this correction

Data Analysis Script

- In file `epi_r1_decon`:

```
waver -GAM
      -input epi_r1_stim.1D
      -TR 2.5
      > epi_r1_ideal.1D

3dvolreg -base 2
         -prefix epi_r1_reg
         -1Dfile epi_r1_mot.1D
         -verb
         epi_r1+orig

3dDeconvolve
  -input epi_r1_reg+orig
  -nfirst 2
  -num_stimts 1
  -stim_file 1 epi_r1_ideal.1D
  -stim_label 1 Allstim
  -tout
  -bucket epi_r1_func
  -fitts epi_r1_fitts
```

\ • waver creates model time series
 \ from input stimulus timing in file
 \ `epi_r1_stim.1D`

\ • Plot a 1D file to screen with
 \ `1dplot epi_r1_ideal.1D`

\ 3dvolreg (3D image registration)
 \ will be covered in a later presentation

\ • 3dDeconvolve = regression code

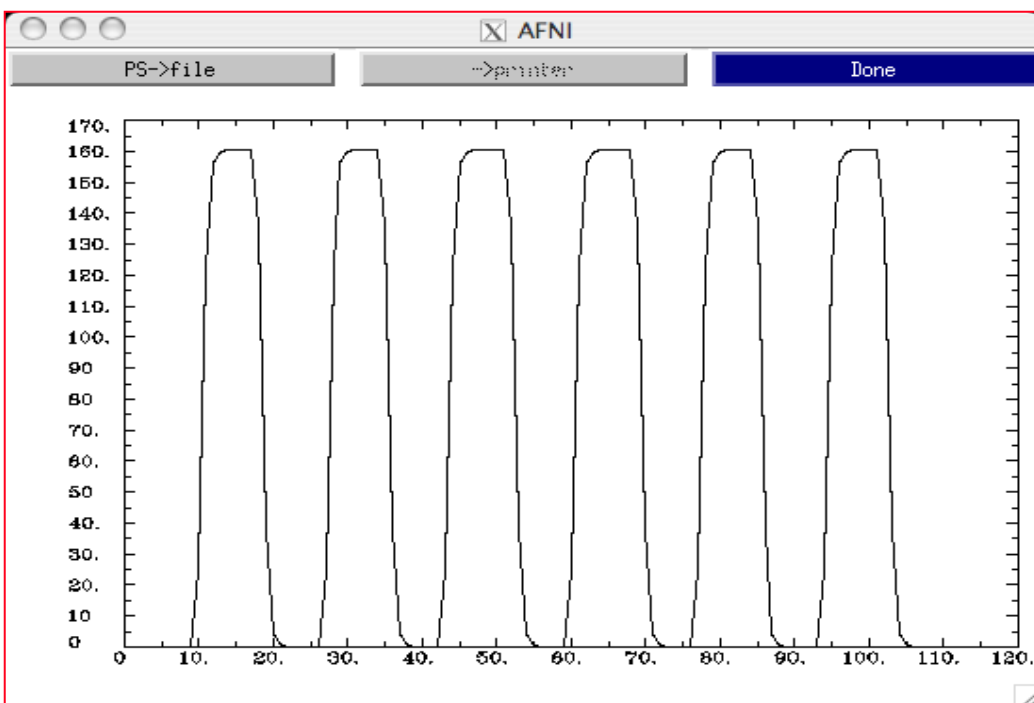

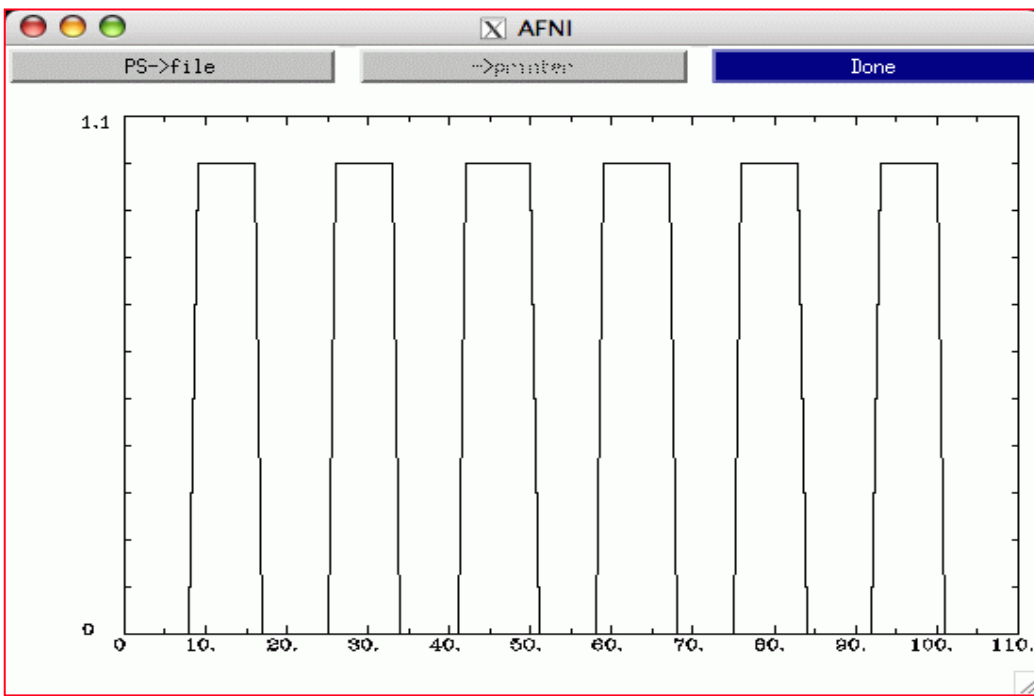

- \ ←• Name of input dataset
- \ ←• Index of first sub-brick to process
- \ ←• Number of input model time series
- \ ←• Name of first input model time series file
- \ ←• Name for results in AFNI menus
- \ ←• Indicates to output t -statistic for β weights
- \ ←• Name of output “bucket” dataset (statistics)
- \ ←• Name of output model fit dataset

- 1 line per time point
- TR=2.5 s
- 0=stim OFF
- 1=stim ON
- Note that “ideal” is delayed from stimulus
- Graphs at right created with 1dplot

To Run Script and View Results

- type **source epi_r1_decon** ; then wait for programs to run
- type **afni** to view what we've got
 - ☞ **Switch Underlay** to epi_r1_reg (output from **3dvolreg**)
 - ☞ **Switch Overlay** to epi_r1_func (output from **3dDeconvolve**)
 - ☞ **Sagittal Image** and **Graph** viewers
 - ☞ **FIM→Ignore→2** to have graph viewer not plot 1st 2 time pts
 - ☞ **FIM→Pick Ideal** ; pick **epi_r1_ideal.1D** (output from **waver**)
- Define Overlay to set up functional coloring
 - **Olay→Allstim[0] Coef** (sets coloring to be from model fit β)
 - **Thr→Allstim[0] t-s** (sets threshold to be model fit t -statistic)
 - **See Overlay** (otherwise won't see the function!)
 - Play with threshold slider to get a meaningful activation map (e.g., $t=4$ is a decent threshold)

Textual Output of the `epi_r1_decon` script

- 3dvolreg output

```

++ Program 3dvolreg: AFNI version=AFNI_2005_12_30_0934 [32-bit]
++ Authored by: RW Cox
++ Reading input dataset ./epi_r1+orig.BRIK
++ Edging: x=3 y=3 z=1
++ Initializing alignment base
++ Starting final pass on 110 sub-bricks: 0..1..2..3.. *** ..106..107..108..109..
++ CPU time for realignment=8.82 s [=0.0802 s/sub-brick]

```

- If a program crashes, we'll need to see this textual output!

More Viewing the Results

- Graph viewer: **Opt**→**Tran 1D**→**Dataset #N** to plot the model fit dataset output by **3dDeconvolve**
 - Will open the control panel for the **Dataset #N** plugin
 - Click first **Input** on ; then choose **Dataset epi_r1_fitts+orig**
 - Also choose **Color dk-blue** to get a pleasing plot
 - Then click on **Set+Close** (to close the plugin panel)
 - Should now see fitted time series in the graph viewer instead of data time series
 - Graph viewer: click **Opt**→**Double Plot**→**Overlay** on to make the fitted time series appear as an overlay curve
 - This tool lets you visualize the quality of the data fit
- Can also now overlay function on MP-RAGE anatomical by using **Switch Underlay** to **anat+orig** dataset
 - Probably won't want to graph the **anat+orig** dataset!

Stimulus Correlated Movement?

- Extensive “activation” (i.e., correlation of data time series with model time series) along the top of the brain is an indicator of stimulus correlated motion artifact
- Can remain even after registration, due to errors in registration, magnetic field inhomogeneities, etc.
- Can be partially removed by using the estimated movement history (from **3dvolreg**) as additional baseline model functions

- **3dvolreg** saved the motion parameters estimates into file **epi_r1_mot.1D**
- For fun: **1dplot epi_r1_mot.1D**

Removing Residual Motion Artifacts

- Last part of script **epi_r1_decon**:

```
3dDeconvolve \
  -input epi_r1_reg+orig \
  -nfirst 2 \
  -num_stimts 7 \
  -stim_file 1 epi_r1_ideal.1D \
  -stim_label 1 AllStim \
  -stim_file 2 epi_r1_mot.1D'[0]' \
  -stim_base 2 \
  -stim_file 3 epi_r1_mot.1D'[1]' \
  -stim_base 3 \
  -stim_file 4 epi_r1_mot.1D'[2]' \
  -stim_base 4 \
  -stim_file 5 epi_r1_mot.1D'[3]' \
  -stim_base 5 \
  -stim_file 6 epi_r1_mot.1D'[4]' \
  -stim_base 6 \
  -stim_file 7 epi_r1_mot.1D'[5]' \
  -stim_base 7 \
  -tout \
  -bucket epi_r1_func_mot \
  -fitts epi_r1_fitts_mot
```

These new lines add 6 regressors to the model and assign them to the baseline (-stim_base option)

Output files: take a moment to look at results

Some Results: Before and After

Before: movement parameters
are not in baseline model

After: movement parameters
are in baseline model

t -statistic threshold set to a p -value of 10^{-4} in both images

Multiple Stimulus Classes

- The experiment analyzed here in fact is more complicated
 - ☞ There are 4 related visual stimulus types
 - ☞ One goal is to find areas that are differentially activated between these different types of stimuli
 - ☞ We have 4 imaging runs, 108 useful time points each (skipping first 2 in each run) that we will analyze together
 - Already registered and put together into dataset **rall_vr+orig**
 - ☞ Stimulus timing files are in subdirectory **stim_files/**
 - ☞ Script file **waver_ht2** will create HRF models for regression:

```
cd stim_files
waver -dt 2.5 -GAM -input scan1to4a.1D > scan1to4a_hrf.1D
waver -dt 2.5 -GAM -input scan1to4t.1D > scan1to4t_hrf.1D
waver -dt 2.5 -GAM -input scan1to4h.1D > scan1to4h_hrf.1D
waver -dt 2.5 -GAM -input scan1to4l.1D > scan1to4l_hrf.1D
cd ..
```
 - ☞ Type **source waver_ht2** to run this script
 - Might also use **1dplot** to check if input .1D files are reasonable

Regression with Multiple Model Files

- Script file **decon_ht2** does the job:

```
3dDeconvolve -xout -input rall_vr+orig \
  -num_stimts 4 \
  -stim_file 1 stim_files/scan1to4a_hrf.1D -stim_label 1 Actions \
  -stim_file 2 stim_files/scan1to4t_hrf.1D -stim_label 2 Tool \
  -stim_file 3 stim_files/scan1to4h_hrf.1D -stim_label 3 HighC \
  -stim_file 4 stim_files/scan1to4l_hrf.1D -stim_label 4 LowC \
  -concat contrasts/runs.1D \
  -glt 1 contrasts/contr_AvsT.txt -glt_label 1 AvsT \
  -glt 1 contrasts/contr_HvsL.txt -glt_label 2 HvsL \
  -glt 1 contrasts/contr_ATvsHL.txt -glt_label 3 ATvsHL \
  -full_first -fout -tout \
  -bucket func_ht2
```

- Run this script by typing **source decon_ht2** (takes a few minutes)

- Stim #1 = visual presentation of active movements
- Stim #2 = visual presentation of simple (tool-like) movements
- Stims #3 and #4 = high and low contrast gratings

Regressors for This Script

via **1dgrayplot**
or **-xjpeg** option

via **1dplot**
on **-stim_file** inputs

Extra Features of 3dDeconvolve - 1

`-concat contrasts/runs.1D` = file that indicates where new imaging runs start

0
108
216
324

`-full_first` = put **full model** statistic first in output file, not last

`-fout -tout` = output both F - and t -statistics

- The full model statistic is an F -statistic that shows how well the sum of all 4 input model time series fits voxel time series data
- The individual models also will get individual F - and t -statistics indicating the significance of their individual contributions to the time series fit
 - ✎ i.e., F_{Actions} tells if model (**Actions+HighC+LowC+Tools+baseline**) explains more of the data variability than model (**HighC+LowC+Tools+baseline**) — with **Actions** omitted

Extra Features of 3dDeconvolve - 2

```
-glt 1 contrasts/contr_AvsT.txt      -glt_label 1 AvsT
-glt 1 contrasts/contr_HvsL.txt      -glt_label 2 HvsL
-glt 1 contrasts/contr_ATvsHL.txt    -glt_label 3 ATvsHL
```

- **GLTs** are General Linear Tests
- **3dDeconvolve** provides tests for each regressor separately, but if you want to test combinations or contrasts of the β weights in each voxel, you need the **-glt** option
- File **contrasts/contr_AvsT.txt** = **0 0 0 0 0 0 0 0 1 -1 0 0**
 (one line with 12 numbers)

8 zeros: could also write 8@0
- Goal is to test a linear combination of the β weights
 - ☞ In this data, we have 12 β weights: 8 baseline parameters (2 per imaging run), which are first in the β vector, and 4 regressor magnitudes, which are from **-stim_file** options
 - ☞ This particular test contrasts the Actions and Tool β s
 - tests if $\beta_{\text{Actions}} - \beta_{\text{Tool}} \neq 0$

Extra Features of 3dDeconvolve - 3

- File `contrasts/contr_HvsL.txt` = `0 0 0 0 0 0 0 0 0 0 1 -1`
 - Goal is to test if $\beta_{\text{HighC}} - \beta_{\text{LowC}} \neq 0$
- File `contrasts/contr_ATvsHL.txt` = `0 0 0 0 0 0 0 0 1 1 -1 -1`
 - Goal is to test if $(\beta_{\text{Actions}} + \beta_{\text{Tool}}) - (\beta_{\text{HighC}} + \beta_{\text{LowC}}) \neq 0$
 - Regions where this statistic is significant will have had different amounts of BOLD signal change in the activity viewing tasks versus the grating viewing tasks
 - This is a way to factor out primary visual cortex
- `-glt_label 3 ATvsHL` option is used to attach a meaningful label to the resulting statistics sub-bricks

Results of **decon_ht2** Script

• Menu showing labels from **3dDeconvolve** run

• Images showing results from third contrast: **ATvsHL**

• Play with this yourself to get a feel for it

Statistics from 3dDeconvolve

- An *F*-statistic measures significance of how much a model component reduced the variance of the time series data
- Full *F* measures how much the signal regressors reduced the variance over just the baseline regressors (**sub-brick #0 below**)
- Individual partial-model *F*s measures how much each individual signal regressor reduced data variance over the full model with that regressor excluded (**sub-bricks #19, #22, #25, and #28 below**)

- The **Coef** sub-bricks are the β weights (e.g., **#17, #20, #23, #26**)
- A *t*-statistic sub-brick measure impact of one coefficient

Alternative Way to Run **waver**

Instead of giving stimulus timing on TR-grid as set of 0s and 1s

- Can give the actual stimulus times (in seconds) using the **-tstim** option

waver -dt 1.0 -GAM -tstim 3 12 17 | 1dplot -stdin

- If times are in a file, can use **-tstim `cat filename`** to place them on the command line after **-tstim** option

☞ This is most useful for event-related experiments, where the timing of stimuli is usually given explicitly

Note backward single quotes

Alternative Way to Run 3dDeconvolve

Instead of giving stimulus timing to **waver**

- Can give the actual stimulus times (in seconds) directly to **3dDeconvolve** using the **-stim_times** option (instead of **-stim_file** as before)
- The program will do the equivalent of **waver** inside itself to generate the necessary column(s) in the **R** matrix
- More information in the latter part of this presentation
 - ☞ Is coupled with the ideas needed for “deconvolution”
 - ☞ Besides input file with stimulus times, must also specify the HRF model to be used with those times
 - That is, which shape(s) are to be placed down at each stimulus time to model the ideal response

Deconvolution Signal Models

- Simple or Fixed-shape regression (previous):
 - ☞ We fixed the shape of the HRF — amplitude varies
 - ☞ Used waver to generate the signal model from the stimulus timing (or could use 3dDeconvolve directly)
 - ☞ Found the amplitude of the signal model in each voxel — solution to the set linear equations = β weights
- Deconvolution or Variable-shape regression (next):
 - ☞ We allow the shape of the HRF to vary in each voxel, for each stimulus class
 - ☞ Appropriate when you don't want to over-constrain the solution by assuming an HRF shape
 - ☞ **Caveat:** need to have enough time points during the HRF in order to resolve its shape

Deconvolution: Pros and Cons

- + Letting HRF shape varies allows for subject and regional variability in hemodynamics
- + Can test HRF estimate for different shapes; e.g., are later time points more “active” than earlier?
 - Need to estimate more parameters for each stimulus class than a fixed-shape model (e.g., 4-15 vs. 1 parameter=amplitude of HRF)
 - Which means you need more data to get the same statistical power (assuming that the fixed-shape model you would otherwise use was in fact “correct”)
 - Freedom to get any shape in HRF results can give weird shapes that are difficult to interpret

Expressing HRF via Regression Unknowns

- The tool for expressing an unknown function as a finite set of numbers that can be fit via linear regression is an **expansion in basis functions**

$$h(t) = \beta_0 \psi_0(t) + \beta_1 \psi_1(t) + \beta_2 \psi_2(t) + \text{☹} = \sum_{q=0}^{q=p} \beta_q \psi_q(t)$$

- ☞ The basis functions $\psi_q(t)$ are known, as is the expansion order p
 - ☞ The unknowns to be found (in each voxel) comprises the set of weights β_q for each $\psi_q(t)$
- Since β weights appear only by multiplying known values, and HRF only appears in final signal model by linear convolution, resulting signal model is still solvable by linear regression

Basis Function: “Sticks”

- The set of basis functions you use determines the range of possible HRFs that you can compute
- “Stick” (or Dirac delta) functions are very flexible

⚠ But they come with a strict limitation

- $\delta(t)$ is 1 at $t=0$ and is 0 at all other values of t
- $\psi_q(t) = \delta(t - q \cdot TR)$ for $q=0, 1, 2, \dots, p$

- $\Rightarrow h(0) = \beta_0$
- $\Rightarrow h(TR) = \beta_1$
- $\Rightarrow h(2 \cdot TR) = \beta_2$
- $\Rightarrow h(3 \cdot TR) = \beta_3$
- $\Rightarrow et cetera$
- $\Rightarrow h(t) = 0$ for any t not on the TR grid

Each piece of $h(t)$ looks like a stick poking up

Sticks: Good Points

- Can represent arbitrary shapes of the HRF, up and down, with ease
- Meaning of each β_q is completely obvious
 - ☞ Value of HRF at time lag $q \cdot TR$ after activation
- **3dDeconvolve** is set up to deal with stick functions for representing HRF, so using them is very easy
 - What is called p here is given by command line option **-stim_maxlag** in the program
 - When choosing p , rule is to estimate longest duration of neural activation after stimulus onset, then add 10-12 seconds to allow for slowness of hemodynamic response

Sticks and TR-locked Stimuli

- This limitation means that, using stick functions as our basis set, we can only model stimuli that are “locked” to the TR grid
 - ☞ That is, stimuli/activations don’t occur at fully general times, but only occur at integer multiples of TR
- For example, suppose an activation is at $t=1.7 \cdot TR$
 - ☞ We need to model the response at later times, such as $2 \cdot TR$, $3 \cdot TR$, etc., so need to model $h(t)$ at times such as $t=(2 \uparrow 1.7) \cdot TR=0.3 \cdot TR$, $t=1.3 \cdot TR$, etc., after the stimulus
- But the stick function model doesn’t allow for such intermediate times
 - **or**, can allow Δt for sticks to be a fraction of TR for data
 - e.g., $\Delta t = TR/2$, which implies twice as many β_q parameters to cover the same time interval (time interval needed is set by hemodynamics)
 - then would allow stimuli that occur on TR-grid or halfway in-between

Deconvolution and Collinearity

- Regular stimulus timing can lead to collinearity!

Equations at each time point:
Cannot tell β_0 from β_4 ,
or β_1 from β_5

β_0	β_1	β_2	β_3	β_0	β_1	β_2	β_3	β_0	β_1	β_2	β_3
$+\beta_4$	$+\beta_5$			$+\beta_4$	$+\beta_5$			$+\beta_4$	$+\beta_5$		

β_0 β_1 β_2 β_3

β_0 β_1 β_2 β_3 β_4 β_5

β_0 β_1 β_2 β_3 β_4 β_5

HRF from stim #1

β_0 β_1 β_2 β_3 β_4 β_5

stim #1

Tail of HRF from #1 overlaps head of HRF from #2, etc

3dDeconvolve with Stick Functions

- Instead of inputting a signal model time series (e.g., created with **waver** and stimulus timing), you input the stimulus timing directly
 - ☞ Format: a text file with 0s and 1s, 0 at TR-grid times with no stimulus, 1 at time with stimulus
- Must specify the maximum lag (in units of TR) that we expect HRF to last after each stimulus
 - ☞ This requires you to make a judgment about the activation — brief or long?
- **3dDeconvolve** returns estimated values for each β_q , for each stimulus class
 - ☞ Usually then use a GLT to test the HRF (or pieces of it) for significance

Extra Features of 3dDeconvolve - 4

- **-stim_maxlag k p** = option to set the maximum lag to **p** for stimulus timing file **#k** for **k=0,1,2,...**
 - ☞ Stimulus timing file input using command line option **-stim_file k filename** as before
 - ☞ Can also use **-stim_minlag k m** option to set the minimum lag if you want a value **m** different from **0**
 - ☞ In which case there are **p-m+1** parameters in this HRF
- **-stim_nptr k r** = option to specify that there are **r** stimulus subintervals per TR, rather than just 1
 - ☞ This feature can be used to get a finer grained HRF, at the cost of adding more parameters that need to be estimated
 - Need to make sure that the input stimulus timing file (from **-stim_file**) has **r** entries per TR
 - TR for **-stim_file** and for output HRF is data **TR ÷ r**

Script for Deconvolution - The Data

- **cd AFNI_data2**

- ☞ data is in **ED/** subdirectory (10 runs of 136 images each; TR=2 s)
- ☞ script in file **@s1.analyze_ht05** (in **AFNI_data2** directory)
 - stimuli timing and GLT contrast files in **misc_files/**
- ☞ start script **now** by typing **source @s1.analyze_ht05**
 - will discuss details of script while it runs (20+ min?)

- **Event-related study from Mike Beauchamp** ←→

- Formerly LBC/NIMH
- Now UT Houston

- ☞ 10 runs with four classes of stimuli (short videos)
 - Tools moving (e.g., a hammer pounding) - **TM**
 - People moving (e.g., jumping jacks) - **HM**
 - Points outlining tools moving (no objects, just points) - **TP**
 - Points outlining people moving - **HP**
- ☞ Goal is to find if there is an area that distinguishes natural motions (HM and HP) from simpler rigid motions (TM and TP)

Script for Deconvolution - Outline

- Examine each imaging run for outliers: **3dToutcount**
- Time shift each run's slices to a common origin: **3dTshift**
- Registration of each imaging run: **3dvolreg**
- Smooth each volume in space (136 sub-bricks per run): **3dmerge**
- Create a brain mask: **3dAutomask** and **3dcalc**
- Rescale each voxel time series in each imaging run so that its average through time is 100: **3dTstat** and **3dcalc**
 - ☞ If baseline is 100, then a β_q of 5 (say) indicates a 5% signal change in that voxel at time lag # q after stimulus
- Catenate all imaging runs together into one big dataset (1360 time points): **3dTcat**
- Compute HRFs and statistics: **3dDeconvolve**
 - ☞ Each HRF will have 15 time points (lags from 0 to 14) with TR=1.0 s, since input data has TR=2.0 s and we use **-stim_nptr k r** option with **r=2**
- Average together all points of each separate HRF to get average % change in each voxel over 14 s interval: **3dTstat**

Script for Deconvolution - 1

This script is designed to run analyses on a lot of subjects at once. We will only analyze the ED data here. The other subjects will be included in the Group Analysis presentation.

```
#!/bin/tcsh
if ( $#argv > 0 ) then
    set subjects = ( $argv )
else
    set subjects = ED
endif
```

```
#####
# Above command will run script for all our subjects - ED, EE, EF - one after
# the other if, when we execute the script, we type: ./@s1.analyze_ht05 ED EE EF.
# If we type ./@s1.analyze_ht05 or tcsh @s1.analyze_ht05, the script runs only
# for subject ED. The user will then have to go back and edit the script so
# that 'set subjects' = EE and then EF, and then run the script for each subj.
#####
```

```
foreach subj ($subjects)
```

Loop over all subjects
(next 2 slides)

```
cd $subj
```

First step is to change to the directory that has this subject's data

Script for Deconvolution - 2

```
#=====
# time shift, volume register and spatially blur our datasets,
# and remove the first two time points from each run
#=====
```

```
set runs = ( `count -digits 2 1 10` )
foreach run ( $runs )
```

Loop over imaging runs 1..10
(loop continues on next slide)

```
set dset = ${subj}_r${run}+orig.HEAD
```

Shorthand for dataset

```
3dToutcount -automask ${dset}
> toutcount_r${run}.1D
```

Outlier check:
By itself, **3dToutcount**
doesn't change data!
To plot "outlierness":
1dplot toutc_r1.1D

```
3dTshift -tzero 0 -heptic
-prefix ${subj}_r${run}_ts
${dset}
```

Interpolate each voxel's
time series to start at the
time of slice #0

Script for Deconvolution - 3

```
3dvolreg -verbose \
  -base ${subj}_r01_ts+orig'[2]' \
  -prefix ${subj}_r${run}_vr \
  -1Dfile dfile.r${run}.1D \
  ${subj}_r${run}_ts+orig'[2..137]'
```

Image registration
of each run to its
#2 sub-brick

```
3dmerge -1blur_fwhm 4 \
  -doall \
  -prefix ${subj}_r${run}_vr_bl \
  ${subj}_r${run}_vr+orig
```

Lightly blur each 3D
volume in each dataset
to reduce noise and
increase functional
overlap among runs
and among subjects

```
3dAutomask -dilate 1 \
  -prefix mask_r${run} \
  ${subj}_r${run}_vr_bl+orig
```

Make an “inside-the-brain”
mask for this dataset

end

End of loop over imaging runs.

At this point, dataset `${subj}_r${run}_vr_bl`
contains the data for subject `${subj}` and imaging
run `${run}`, which has been time-shifted, realigned,
and blurred; also, a brain-only mask has been made

Script for Deconvolution - 4

```

#=====
# create a union mask from those of the individual runs
#=====

3dcalc -a mask_r01+orig -b mask_r02+orig -c mask_r03+orig \
-d mask_r04+orig -e mask_r05+orig -f mask_r06+orig \
-g mask_r07+orig -h mask_r08+orig -i mask_r09+orig \
-j mask_r10+orig \
-expr 'or(a+b+c+d+e+f+g+h+i+j)' \
-prefix full_mask

```

This mask dataset will be 1 inside the largest contiguous high intensity EPI region, and 0 outside that region — this makes a brain mask

3dcalc program = voxel-wise “calculator” for datasets.

Input is 10 individual run dataset masks (1 in brain, 0 outside).

Output is mask which is

- 1 wherever *any* individual mask is 1,
- 0 wherever *all* individual masks are 0

Script for Deconvolution - 5

```

#=====
# - re-scale each run's mean to 100
# - use full_mask to zero out non-brain voxels
#
# If the mean is 100, and the result of 3dcalc at a voxel is 106 (at
# some time point), then one can say that voxel shows a 6% increase in
# signal activity, relative to the mean.
#=====

```

```

foreach run ( $runs )

```

```

    3dTstat -prefix mean_r${run}
           ${subj}_r${run}_vr_bl+orig \

```

Mean of the runth dataset,
through time: run=1..10

```

    3dcalc -a ${subj}_r${run}_vr_bl+orig \
          -b mean_r${run}+orig \
          -c full_mask+orig \
          -expr "(a/b * 100) * c" \
          -prefix scaled_r${run}

```

- Divide each voxel value ('a') by its temporal mean ('b') and multiply by 100
- Result will have temporal mean of 100
- Voxels not in the mask will be set to 0 (by 'c')

```

    rm -f mean_r${run}+orig*

```

```

end

```

Script for Deconvolution - 6

```
3dTcat -prefix ${subj}_all_runs \  
scaled_r??+orig.HEAD
```

“Gluing” the runs together, since **3dDeconvolve** only operates on one input dataset at a time

```
cat dfile.r??.1D > dfile.all.1D
```

Also “glue” together the movement parameters output from **3dvolreg**

```
#=====\  
# move unloved run data into separate directories\  
#=====
```

```
mkdir runs_orig runs_temp
```

```
mv ${subj}_r*_vr* ${subj}_r*_ts* scaled* \  
dfile.r??.1D toutcount* runs_temp
```

Gets this stuff out of the way so that we don't see it when we run AFNI later

```
mv ${subj}_r* runs_orig
```

Script for Deconvolution - 7

```

3dDeconvolve -polort 2 \
  -input ${subj}_all_runs+orig -num_stimts 10 Input dataset \
  -concat ../misc_files/runs.1D \
  -stim_file 1 ../misc_files/all_stims.1D'[0]' 0-1 stim file #1 \
    -stim_label 1 ToolMovie \
    -stim_minlag 1 0 -stim_maxlag 1 14 -stim_nptr 1 2 \
  -stim_file 2 ../misc_files/all_stims.1D'[1]' 0-1 stim file #2 \
    -stim_label 2 HumanMovie \
    -stim_minlag 2 0 -stim_maxlag 2 14 -stim_nptr 2 2 \
  -stim_file 3 ../misc_files/all_stims.1D'[2]' 0-1 stim file #3 \
    -stim_label 3 ToolPoint \
    -stim_minlag 3 0 -stim_maxlag 3 14 -stim_nptr 3 2 \
  -stim_file 4 ../misc_files/all_stims.1D'[3]' 0-1 stim file #4 \
    -stim_label 4 HumanPoint \
    -stim_minlag 4 0 -stim_maxlag 4 14 -stim_nptr 4 2 \

```

- 4 time series models: one for each the 4 different classes of events
- All stimuli time series in 1 file with 4 columns: `../misc_files/all_stims.1D`
 - Selectors like `'[2]'` pick out a particular column
 - Each stimulus input and HRF output is sampled at $TR/2 = 1.0$ s
 - Due to the use of `-stim_nptr k 2` for each `k`
 - Lag from 0 to 14 s is about right for HRF to a brief stimulus
- `-stim_label` option: names used in AFNI and below in `-gltsym` options

Script for Deconvolution - 8

```

-stim_file 5  dfile.all.1D'[0]' -stim_base 5
-stim_file 6  dfile.all.1D'[1]' -stim_base 6
-stim_file 7  dfile.all.1D'[2]' -stim_base 7
-stim_file 8  dfile.all.1D'[3]' -stim_base 8
-stim_file 9  dfile.all.1D'[4]' -stim_base 9
-stim_file 10 dfile.all.1D'[5]' -stim_base 10

-iresp 1 TMirf -iresp 2 HMirf
-iresp 3 TPirf -iresp 4 HPirf
-full_first -fout -tout -nobout -xjpeg Xmat
-bucket ${subj}_func

```

Movement
regressors-
of-no-interest:
output from
3dvolreg

- Output HRF (**-iresp**) 3D+time dataset for each stimulus class
 - Each of these 4 datasets will have TR=1.0 s and have 15 time points (β weights for lags 0..14)
 - Can plot these HRF datasets atop each other using **Dataset#N** plugin
 - Useful for visual inspection of regions that GLTs tell you have different responses for different classes of stimuli
- **-nobout** = don't output statistics of baseline parameters
- **-bucket** = save statistics into dataset with this prefix
- **-xjpeg** = save an image of the **R** matrix into file **Xmat.jpg**

Script for Deconvolution - 9

```

-GLTSYM ../misc_files/contrast1.1D -glt_label 1 FullF \
-GLTSYM ../misc_files/contrast2.1D -glt_label 2 HvsT \
-GLTSYM ../misc_files/contrast3.1D -glt_label 3 MvsP \
-GLTSYM ../misc_files/contrast4.1D -glt_label 4 HMvsHP \
-GLTSYM ../misc_files/contrast5.1D -glt_label 5 TMvsTP \
-GLTSYM ../misc_files/contrast6.1D -glt_label 6 HPvsTP \
-GLTSYM ../misc_files/contrast7.1D -glt_label 7 HMvsTM

```

- Run many GLTs to contrast various pairs and quads of cases
- New feature: **-GLTSYM** = specify β weights to contrast using **-stim_label** names given earlier on the command “line”
 - Simpler than counting 0s and ± 1 s to fill out GLT matrix numerically
- Example: file **contrast2.1D** is the single line below:

```
-ToolMovie +HumanMovie -ToolPoint +HumanPoint
```

 which means to put “-1” in the matrix for all 15 lags for stimuli #1 and #3 and “+1” in the matrix for all 15 lags for stimuli #2 and #4
 - This is the “Human vs Tools” contrast (labeled **HvsT** via **-glt_label**)
 - Sum of the 30 “Tool” β weights subtracted from Sum of the 30 “Human” β weights
 - Testing: % signal change for Human stimuli different than Tool stimuli?

Script for Deconvolution - 10

```
3dbucket -prefix ${subj}_func_slim -fbuc \
        ${subj}_func+orig'[0,125..151]'
```

Extract a subset of interesting statistics sub-bricks into a “slimmed-down” functional dataset

```
foreach cond (TM HM TP HP)
```

```
    3dTstat -prefix ${subj}_${cond}_irf_mean \
            ${cond}irf+orig
```

Compute HRF means across all lags 0..14 for each of the 4 stimuli types

```
    adwarp -apar ${subj}spgr+tlrc -dxyz 3 \
            -dpar ${subj}_${cond}_irf_mean+orig
```

Transform this individual’s mean % signal results into Talairach coordinates for group analyses

```
end
```

```
cd ..
end
```

End of loop over subjects; go back to upper directory whence we started

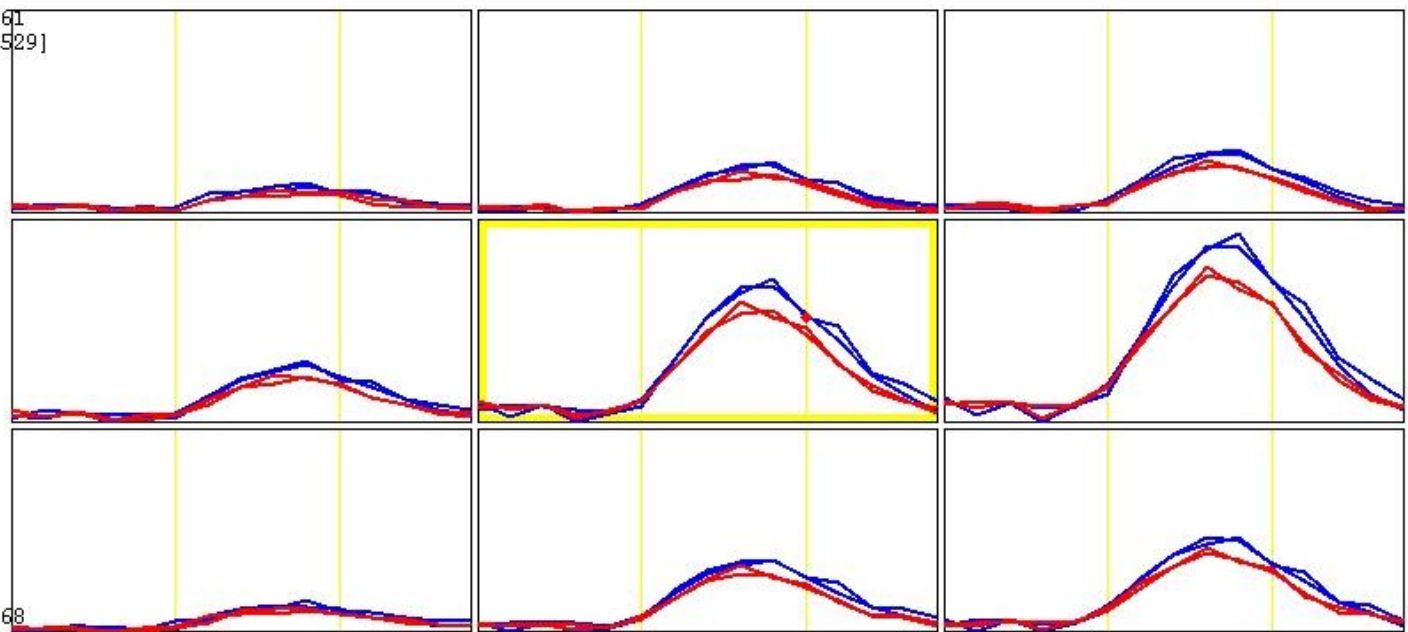

```
#####
# End of script!
# Take ${subj}_${cond}_irf_mean+tlrc datasets into 3dANOVA3
#####
```

Results: Humans vs. Tools

[A] AFNI: AFNI_data2/ED/HMirf+orig & ED_HM_irf_mean+orig

6.37761
[+6.823529]

- Color overlay is **HvsT** contrast
- **Blue** (upper) curves: Human HRFs
- **Red** (lower) curves: Tool HRFs

Yet More Fun 3dDeconvolve Options

- **-mask** = used to turn off processing for some voxels
 - ☞ speed up the program by not processing non-brain voxels
- **-input1D** = used to process a single time series, rather than a dataset full of time series
 - ☞ test out a stimulus timing sequence
 - ☞ **-nodata** option can be used to check for collinearity
- **-censor** = used to turn off processing for some time points
 - ☞ for time points that are “bad” (e.g., too much movement)
- **-sresp** = output standard deviation of HRF estimates
 - ☞ can plot error bands around HRF in AFNI graph viewer
- **-errts** = output residuals (i.e., difference between fitted model and data)
 - ☞ for statistical analysis of time series noise
- **-jobs *N*** = run with multiple CPUS — *N* of them
 - ☞ extra speed, if you have a dual-CPU system (or more)!

3dDeconvolve with Free Timing

- The fixed-TR stick function approach doesn't work well with arbitrary timing of stimuli
 - ☞ When subject actions/reactions are self-initiated, timing of activations cannot be controlled
- If you want to do deconvolution (vs. fixed-shape analysis), then must adopt a different basis function expansion approach
 - ☞ One that has a finite number of parameters but also allows for calculation of $h(t)$ at any arbitrary point in time
- Simplest set of such functions are closely related to stick functions: tent functions

$$T(x) = \begin{cases} 1 - |x| & \text{for } -1 < x < 1 \\ 0 & \text{for } |x| > 1 \end{cases}$$

Tent Functions = Linear Interpolation

- Expansion in a set of spaced-apart tent functions is the same as linear interpolation

$$\beta_0 \cdot T\left(\frac{t}{L}\right) + \beta_1 \cdot T\left(\frac{t-L}{L}\right) + \beta_2 \cdot T\left(\frac{t-2 \cdot L}{L}\right) + \beta_3 \cdot T\left(\frac{t-3 \cdot L}{L}\right) + \dots$$

- Tent function parameters are also easily interpreted as function values (e.g., β_2 = response at time $t = 2 \cdot L$ after stim)
- User must decide on relationship of tent function grid spacing L and time grid spacing TR (usually would choose $L \geq TR$)
- Fancy name for tent functions: piecewise linear B-splines

Tent Functions: Average Signal Change

- For input to group analysis, usually want to compute average signal change
 - ☞ Over entire duration of HRF (usual)
 - ☞ Over a sub-interval of the HRF duration (sometimes)
- In previous slide, with 6 β weights, average signal change is

$$\frac{1}{2}\beta_0 + \beta_1 + \beta_2 + \beta_3 + \beta_4 + \frac{1}{2}\beta_5$$

- First and last β weights are scaled by half since they only affect half as much of the duration
- In practice, may want to use $0 \cdot \beta_0$ since immediate post-stimulus response is not hemodynamically correct
- β weights are output into the “bucket” dataset produced by **3dDeconvolve**
- Can then be combined into a single number using **3dcalc**

3dDeconvolve -stim_times

- Direct input of stimulus timing, plus a response model
- Specifies stimuli, instead of using `-stim_file`
- `-stim_times k tname rtype`
 - ✎ `k` = stimulus index (from 1 to `-num_stimts` value)
- `tname` = name of `.1D` file containing stimulus times (seconds)
 - ✎ **N.B.:** TR stored in dataset header must be correct!
- `rtype` = name of response model to use for each stimulus time read from `tname` file
 - ✎ **GAM** = gamma variate function from `waver` (fixed-shaped analysis)
 - ✎ **TENT(b, c, n)** = tent function deconvolution, ranging from time `s+b` to `s+c` after each stimulus time `s`, with `n` basis functions (divided evenly over `c-b` seconds, into `n-1` intervals)
 - ✎ several other `rtype` options available (experimental)
- Can mix `-stim_file` and `-stim_times` as needed
 - ✎ e.g., movement parameter regressors at each TR

Two Possible Formats of Timing File

- A single column of numbers
 - ☞ One stimulus time per row
 - ☞ Times are relative to first image in dataset being at $t=0$
 - ☞ May not be simplest to use if multiple runs are catenated
- One row for each run within a catenated dataset
 - ☞ Each time in j^{th} row is relative to start of run $\#j$ being $t=0$
 - ☞ If some run has NO stimuli in the given class, just put a single “*” in that row as a filler
 - Different numbers of stim per run are OK
 - At least one row must have more than 1 time
(so that this type of timing file can be told from the other)
- Two methods are available because of users’ diverse needs
 - ☞ **N.B.:** if you chop first few images off the start of each run, the inputs to `-stim_times` must be adjusted accordingly

```

9.6
11.8
19.4
```

```
4.7 9.6 11.8 19.4
*
8.3 10.6
```

Other Recent-ish Upgrades

- See <http://afni.nimh.nih.gov/doc/misc/3dDeconvolveSummer2004/>
- Equation solver: Gaussian elimination to compute **R** matrix pseudo-inverse was replaced by SVD (like principal components)
 - ✎ Advantage: smaller sensitivity to computational errors
 - ✎ “Condition number” and “inverse error” values are printed at program startup, as measures of accuracy of pseudo-inverse
 - ✎ Condition number < 1000 is good
 - ✎ Inverse error < 1.0e-10 is good
- **3dDeconvolve_f** program can be used to compute in single precision (7 decimal places) rather than double precision (16)
 - ✎ For better speed, but with lower numerical accuracy
 - ✎ Best to do at least one run **both** ways to check if results differ significantly (SVD solver *should* be safe)

Recent Upgrades - 2

- New `-xjpeg xxx.jpg` option will save a JPEG image file of the columns of the **R** matrix into file `xxx.jpg` (and an image of the pseudo-inverse of **R** into file `xxx_psinv.jpg`)

Constant and linear baselines for each run (`-polort 1`)

Simple regression functions created by `waver` and input by `-stim_file`

Why 'x' instead of 'R'? Because SPM calls this the 'X' matrix, not the 'R' matrix.

Recent Upgrades - 3

- Matrix inputs for `-glt` option can now indicate lots of zero entries using a notation like `30@0 1 -1 0 0` to indicate that 30 zeros precede the rest of the input line
 - ✎ Example: 10 imaging runs and `-polort 2` for baseline
 - ✎ Can put comments into matrix and .1D files, using lines that start with `#` or `//`
 - ✎ Can use `\` at end of line to specify continuation
- Matrix input for GLTs can also be expressed symbolically, using the names given with the `-stim_label` options:

```
-stim_label 1 Ear -stim_maxlag 1 4
```

```
-stim_label 2 Wax -stim_maxlag 2 4
```

✎ Old style GLT might be

```
{zeros for baseline} 0 0 1 1 1 0 0 -1 -1 -1
```

Sum of Ear – Sum of Wax (lags 2..4)

✎ New style (via `-gltsym` option) is

```
Ear[2..4] -Wax[2..4]
```

Recent Upgrades - 4

- New **-xsave** option saves the **R** matrix (and other info) into a file that can be used later with the **-xrestore** option to calculate some extra GLTs, without re-doing the entire analysis (goal: save some time by not recomputing)
- **-input** option now allows multiple 3D+time datasets to be specified to automatically concatenate individual runs into one file 'on the fly'
 - ✎ Avoids having to use program **3dTcat**
 - ✎ User must still supply full-length **.1D** files for the various input time series (e.g., **-stim_file**, **-stim_times**)
 - ✎ **-concat** option will be ignored if this option is used
 - Break points between runs will be taken as the break points between the various **-input** datasets
- **-polort** option now uses Legendre polynomials instead of simple $1, t, t^2, t^3, \dots$ basis functions (more numerical accuracy)

Recent Upgrades - 5

- **3dDeconvolve** now checks for duplicate `-stim_file` names and for duplicate matrix columns, and prints warnings
 - ↳ These are not fatal errors
 - If the same regressor is given twice, each copy will only get half the amplitude (the “beta weight”) in the solution
- All-zero regressors are now allowed
 - ↳ Will get zero weight in the solution
 - A warning message will be printed to the terminal
 - ↳ Example: task where subject makes a choice for each stimulus (e.g., male or female face?)
 - You want to analyze correct and incorrect trials a separate cases
 - What if a subject makes no mistakes? Hmmm...

Recent Upgrades - 6

- Recall: `-iresp` option outputs the HRF model for one stimulus
 - ☞ When used with `-stim_times`, values are usually output using the dataset TR time spacing
 - ☞ Can change to a different grid via new `-TR_times dt` option, which sets the output grid spacing for `-iresp` to `dt` for HRF models computed via `-stim_times`
 - Is useful for producing nice smooth pictures of HRF
 - Also works with `-sresp` option (= std.dev. of HRF)
- **Difficulty**: using GLTs with results from `-stim_times`
 - ☞ GLTs operate on regression coefficients
 - ☞ For advanced (experimental) `rtype` models, regression coefficients don't correspond directly to HRF amplitudes
 - Exceptions: **GAM, TENT, BLOCK**

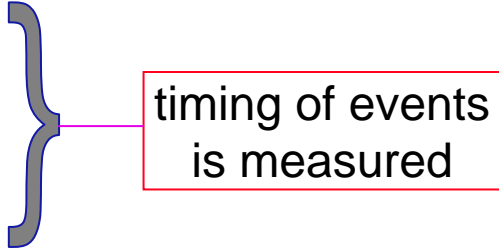

Upgrades – *Planned* or *Dreamed of*

- Automatic baseline normalization of input time series
- Automatic mask generation (à la **3dAutomask** program)
- Spatial blur (à la **3dmerge -lblur**)
- Time shift input before analysis (à la **3dTshift** program)
- Negative lags for **-stim_file** method of deconvolution
 - ☞ for pre-stimulus cognition/anticipation
 - ☞ **-stim_times** already allows pre-stimulus response
- ‘Area under curve’ addition to **-gltsym** to allow testing of pieces of HRF models from **-stim_times**
- Slice- and/or voxel-dependent regressors
 - ☞ For physiological noise cancellation, etc.
- Floating point output format
 - ☞ Currently is shorts + scale factor

Advanced Topics in Regression

- Can have activations with multiple phases that are not always in the same time relationship to each other; e.g.:
 - a) subject gets cue #1
 - b) variable waiting time (“hold”)
 - c) subject gets cue #2, emits response
 - ↳ which depends on both cue #1 and #2
- } timing of events is known
- ☞ Cannot treat this as one event with one HRF, since the different waiting times will result in different overlaps in separate responses from cue #1 and cue #2
 - ☞ Solution is multiple HRFs: separate HRF (fixed shape or deconvolution) for cue #1 times and for cue #2 times
 - Must have significant variability in inter-cue waiting times, or will get a nearly-collinear model
 - ↳ impossible to tell tail end of HRF #1 from the start of HRF #2, if always locked together in same temporal relationship
 - How much variability is “significant”? Good question.

Even More Complicated Case

- Solving a visually presented puzzle:
 - a) subject sees puzzle
 - b) subject cogitates a while
 - c) subject responds with solution
- The problem is that we expect some voxels to be significant in phase (b) as well as phases (a) and/or (c)
- Variable length of phase (b) means that shape for its response varies between trials
 - ☞ Which is contrary to the whole idea of averaging trials together to get decent statistics (which is basically what linear regression amounts to, in a fancy sort of way)
- Could assume response **amplitude** in phase (b) is constant across trials, and response **duration** varies directly with time between phases (a) and (c)
 - ☞ Need three HRFs; phase (b)'s is a little tricky to generate using waver, but it could be done

Noise Issues

- “Noise” in fMRI is caused by several factors, not completely characterized
 - ✎ MR thermal noise (well understood, unremovable)
 - ✎ Cardiac and respiratory cycles (partly understood)
 - In principle, could measure these sources of noise separately and then try to regress them out
 - ↳ RETROICOR program underway (R Birn & M Smith of FIM/NIMH)
 - ✎ Scanner fluctuations (e.g., thermal drift of hardware)
 - ✎ Small subject head movements (10-100 μ m)
 - ✎ Very low frequency fluctuations (periods longer than 100 s)
- Data analysis should try to remove what can be removed and allow for the statistical effects of what can't be removed
 - ✎ “Serial correlation” in the noise time series affects the t - and F -statistics calculated by **3dDeconvolve**
 - ✎ At present, nothing is done to correct for this effect (by us)

Nonlinear Regression

- Linear models aren't everything
 - 👉 e.g., could try to fit HRF of the form $h(t) = a \cdot t^b \cdot e^{-t/c}$
 - 👉 Unknowns **b** and **c** appear nonlinearly in this formula
- Program **3dNLFit** can do nonlinear regression (including nonlinear deconvolution)
 - 👉 User must provide a C function that computes the model time series, given a set of parameters (e.g., **a**, **b**, **c**)
 - 👉 Program then drives this C function repeatedly, searching for the set of parameters that best fit each voxel
 - 👉 Has been used to fit pharmacological wash-in/wash-out models (difference of two exponentials) to fMRI data acquired during pharmacological challenges
 - e.g., injection of nicotine, cocaine, etc.
 - these are tricky experiments, at best
